9) Implement unification using first order logic

Start

Input two expressions E1 and E2
If E1 = E2
    print "Already unified"

If predicate names are different
print "Unification failed"

If no. of arguments are different
print "Unification failed"

For each pair of arguments in E1 and E2
    If both arguments are constants
        If constants are different
            print "unification failed"

    Else if one argument is a variable
        Substitute variable with the other argument

    Else
        Compare the arguments recursively
    Endif
End for

print "unification successful"

print (substitutions)

Stop

output:

Enter first expression: Eats (x, apple)
Enter second expression: Eats (Riya, y)
Unification successful.
Substitutions:
x= Riya
y= Apple
Unified Expression: Eats (x, apple)
